Sleep Dashboard

Two-Week Overview | 9 – 22 February 2026

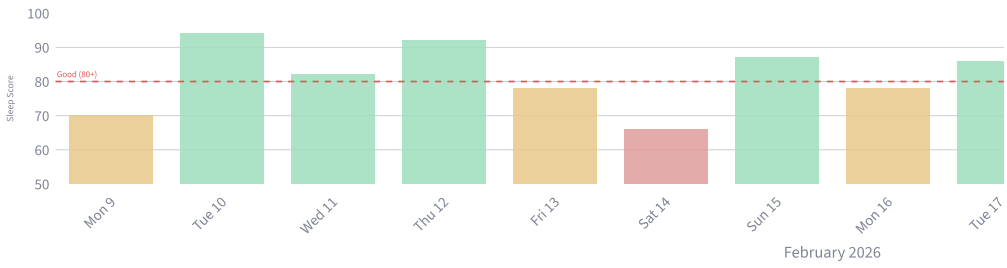
Here's your overview of 14 nights (9–22 February 2026). It covers your **nightly sleep scores, duration, and deep sleep**, the **four bedroom conditions that affected your sleep** (noise variability, humidity, noise level, and temperature stability), and **outdoor air quality** around your home.

Colour key across all charts: Good sleep (score ≥ 80) · Fair sleep (70–79) · Poor sleep (score < 70)

Sleep Overview

AVERAGE SLEEP SCORE	AVERAGE DURATION	AVERAGE DEEP SLEEP
82 / 100	7.9 hrs	2.4 hrs

Nightly Sleep Score



Sleep scores are provided by the Ultrahuman Ring. Score categories (Excellent, Good, Fair, Poor) are defined by this dashboard and are not official Ultrahuman classifications.

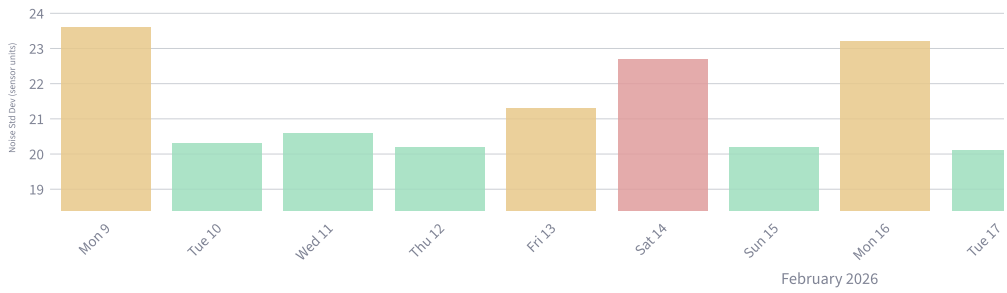
Bedroom Environment

AVERAGE NOISE VARIABILITY	AVERAGE HUMIDITY	AVERAGE NOISE LEVEL	AVERAGE TEMP RANGE
21.3	51 %	78	1.5 °C

These are the four bedroom conditions that showed a statistically significant correlation with your sleep score across 14 nights, ordered by strength of association. Select each tab below to see how it varied night to night.

Noise Variability | Humidity | Noise Level | Temperature Stability

Nightly Noise Variability

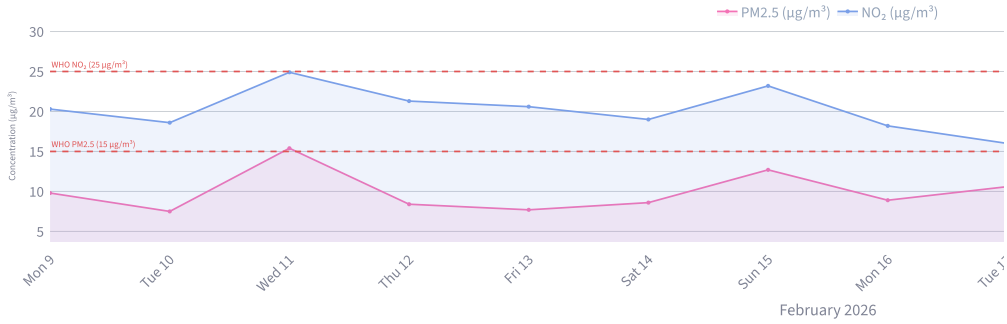


Standard deviation of noise readings per night. Higher values mean more fluctuation in noise levels (e.g. intermittent traffic, doors closing).

External Air Quality

OUTSIDE WHO PM2.5 GUIDELINE	OUTSIDE WHO NO_2 GUIDELINE
1 / 14 nights	1 / 14 nights

Nightly Air Pollutant Levels



Neither PM2.5 nor NO_2 showed a significant correlation with sleep quality in this dataset. These are included for general health context against WHO guidelines. Air quality data covers the sleep window (11 pm to 9 am) only. WHO guidelines for PM2.5 (15 µg/m³) and NO_2 (25 µg/m³) are based on 24-hour averages, so these comparisons represent partial-day measurements.
